This will cause a different result than what is returned by any of the libraries when looking for the exact string. Regardless of whether you use URLClassLoader or the String's StringBuffer, you will receive the second string. Ideas for your question: Use a String's StringBuffer rather than a URL's String Initial seeding and grafting of mycorrhizal fungi in the field-based study of soil fungal biodiversity. A field-based study was carried out at Schleswig Holstein (Northern Germany) to document and study early plant colonization by soil micro- and mesofungi, using a standardized method. Seedlings of the wildflower *Pedicularis sylvatica* were planted in plots that were seeded with naturally colonized seedlings in spring 1999 and were treated with fungicide or fungicide and mycorrhizal inoculation (MI) in the following spring. A total of nine seedlings were planted per plot. The survival of the donor plants was checked during the first, second and fourth growing season. Seedlings in plot M were treated with fungicide. Seedlings of the other plots (F, E, G, H, J and K) received fungicide as well as additional inoculation by arbuscular mycorrhizal fungi (AM fungi) as described in the paper. The survival of seedlings in F, E, G and J was checked during the first growing season. In the second and fourth growing seasons, the survival of seedlings from plots K, H and M was also checked. Mould development was checked by the substrate test. Roots of donor plants were sampled during the first growing season and seedlings with mycorrhizal colonisation were identified by scanning electron microscopy and laser-induced fluorescence microscopy. In addition, roots of two F, two J, three K and a series of randomly selected plants were sampled from each plot. Fungi were isolated from the roots. The isolates were identified in the laboratory. Conventional culture media and the HNFS (Hermann Federer Schweinitz) medium were used for the culture of AM fungi. Fingerprinting and sequencing of the 18S ribosomal subunit were used for the identification of the isolates. A total of 251 root fragments were sampled, of which 215 were allocated to seedlings. Mycorrhizal colonization of the roots was observed in 99% of the sampled seedlings (41 seedlings were analysed)
